

PHP Task

Let's build some simple single endpoint publicly available REST products api.

Requirements:

The API should be based on the **laravel framework**.

You should make 1 endpoint: to **create a product**.

Product has 2 properties: **name and price**.

So please go ahead and download the latest version of laravel and start coding.

Please keep in mind that even though we take quality of code very seriously, we want to keep this task very simple and it should be used as conversation starter, therefore the following aspects are not part of this exercise:

- Tests
- Linter
- Authentication / Authorization (everything is just publicly available)
- Security
- Containerization (Docker)

However please show us some skills in these aspects instead:

- **SOLID principles**
- **Clean Code**
- **REST principles**
- Design Patterns
- PSR standards

The delivery does not need to include a working code, we will just have a look at your coding style and ask about your decisions.
